Effects of a culturally tailored parenting support programme in Somali-born parents’ mental health and sense of competence in parenting: a randomised controlled trial

Fatumo Osman,1,2 Raziye Salari,3 Marie Klingberg-Allvin,1,2 Ulla-Karin Schön,2 Renée Flacking2

ABSTRACT

Objectives To evaluate the effectiveness of a culturally tailored parenting support programme on Somali-born parents’ mental health and sense of competence in parenting.

Design Randomised controlled trial.

Setting A city in the middle of Sweden.

Participants Somali-born parents (n=120) with children aged 11–16 years and self-perceived stress in their parenting were randomised to an intervention group (n=60) or a waiting-list control group (n=60).

Intervention Parents in the intervention group received culturally tailored societal information combined with the Connect parenting programme during 12 weeks for 1–2 hours per week. The intervention consisted of a standardised training programme delivered by nine group leaders of Somali background.

Outcome The General Health Questionnaire 12 was used to measure parents’ mental health and the Parenting Sense of Competence scale to measure parent satisfaction and efficacy in the parent role. Analysis was conducted using intention-to-treat principles.

Results The results indicated that parents in the intervention group showed significant improvement in mental health compared with the parents in the control group at a 2-month follow-up: B=-3.62, 95% CI 2.01 to 5.18, p<0.001. Further, significant improvement was found for efficacy (B=-6.72, 95% CI -8.15 to -5.28, p<0.001) and satisfaction (B=-4.48, 95% CI -6.27 to -2.69, p<0.001) for parents in the intervention group. Parents’ satisfaction mediated the intervention effect on parental mental health (β=-0.88, 95% CI -1.84 to -0.16, p=0.047).

Conclusion The culturally tailored parenting support programme led to improved mental health of Somali-born parents and their sense of competence in parenting 2 months after the intervention. The study underlines the importance of acknowledging immigrant parents’ need for societal information in parent support programmes and the importance of delivering these programmes in a culturally sensitive manner.

Clinical trial registration NCT02114593.

INTRODUCTION

The process of non-voluntary immigration, transitioning and acculturating to a new country may have a negative impact on the mental health of immigrants.1–3 Postmigration factors (eg, stress, lack of social capital, social isolation and loss of social network) as well as acculturation problems and experiences of discrimination in the host country affect the mental health of the parents and the children.4 5 Moreover, immigrant parents face challenges concerning their role and responsibilities as parents while adjusting to the host country, all of which tend to create stress in parenting.6–8 The mental health problems of parents have been reported to be a risk factor for children’s behavioural problems and may negatively affect the parent–child attachment and their relationship.7 8 Studies have also shown that parents with mental health problems have a low perceived sense of competence in parenting and may lack the ability to employ positive parenting practices.9 10

Studies conducted on different populations have generally demonstrated that parenting support programmes encourage positive
parenting practices, strengthen parent–child relationships and promote the mental health of parents. Previous studies have linked parenting support programmes with an improvement of parents’ sense of competence, which, in turn, has an impact on parents’ mental health. According to Bandura’s theory on self-efficacy, stronger self-efficacy in child rearing leads to better satisfaction in parenting and decreased stress and depression. Some studies have found a positive relationship between parents’ sense of competence and parenting behaviour, and that increased maternal self-efficacy is associated with decreased depressive symptoms in postpartum mothers. To date, it is unclear whether parenting support programmes are effective in improving the mental health of parents directly or via increased self-efficacy and satisfaction in the parenting role.

In addition, little knowledge is available on the effect of parenting support programmes delivered to immigrant parents. The few studies available have mostly shown little or no improvement in the mental health of immigrant parents or even poorer outcomes for immigrant families and families with low socioeconomic status. Scarcity of studies in this area may simply because few immigrant parents participate in such programmes. Several studies have reported difficulties in recruiting and retaining immigrant parents in parenting support programmes. Factors such as belonging to an ethnic minority, low socioeconomic status, practical aspects or experienced alienation and discrimination all contribute to low participation. Other studies have demonstrated that low participation and a high dropout rate of immigrant parents are associated with a lack of cultural sensitivity in the intervention, poor information about the parenting programme and lack of trust towards professionals. A qualitative study conducted with Somali-born parents in Sweden showed that Somali parents experienced many societal challenges in the new country and in their parenting behaviours. The parents expressed a need for specific parental support that focuses on parenting in the new country and on strengthening the parent–child relationship.

In a recent randomised controlled trial (RCT), we showed that an intervention in the form of a culturally tailored parenting support programme was effective in reducing children’s behaviour problems 2 months after the intervention, which was our primary outcome measure of the study. In the current paper, we limited our investigation to two of the eight prespecified secondary outcomes with the aim to evaluate the effectiveness of a culturally tailored parenting support programme on the mental health and sense of competence in the parenting of Somali-born parents. Furthermore, we examined whether the intervention affected the mental health of parents, owing to their new sense of competence.

**Methods**

**Study design and participants**

The study was designed as an RCT to evaluate the effectiveness of a culturally tailored parenting support programme for Somali-born parents living in Sweden. The trial comprised two arms: parents were randomised to either an intervention group or a waiting-list control group. The study was conducted in a city in the middle of Sweden, of which approximately 3000 of the inhabitants are of Somali origin. Parents were recruited through key persons within Somali associations, social services, schools and a family centre (a meeting place for parents living in the city). All Somali-born parents expressing interest were screened for eligibility. Somali-born parents with children aged 11–16 years and with self-perceived stress related to parenting practices were included in the study. Parents with severe mental illness (eg, psychosis, schizophrenia, bipolar disorder) or participating in another parenting programme were excluded. Eligible parents completed a baseline questionnaire before randomisation and at the 2-month follow-up and were given a gift voucher equivalent to Kr 150 (Swedish Kroner) (approximately US$15). Ethical approval for the study was obtained from the Swedish Regional Ethical Review Board in Uppsala, Sweden (Dnr 2014/048). All participants gave both oral and written informed consent.

**Intervention**

The parenting intervention consisted of 12 group-based sessions lasting on average about 1–2 hours, combining culturally tailored societal information with the Connect parenting support programme, which has been described elsewhere. The first two sessions were designed based on results from earlier findings on qualitative focus group discussions. The aim of the culturally tailored societal information aspect of the intervention was to give Somali-born parents an introduction on parenting styles, the rights of the child, the family legal system in relation to parenting and the goal of the work of social services with children and family. The other 10 sessions constituted the Connect parenting support programme. The Connect is a standardised programme based on attachment theory and focuses on strengthening the parent–child relationship and attachment. The content aims to enhance and stimulate parents to reflect on how they respond to their child’s behaviours and to build a trusting and secure relationship. The Connect programme was adapted and modified in relation to role play and examples to make it understandable for the participants without changing the programme’s core components. In total, nine group leaders (five male and four female) of Somali background delivered the intervention. Each session of the Connect programme was administered by two group leaders (one male and one female) together with sex-mixed groups of 12–17 parents. The intervention was held near the participants’ neighbourhood. Participants were offered child care services during the sessions and the possibility for support (eg, in reading letters from the municipality or migration office).
Outcome measures

The main outcome measure was reduced emotional and behavioural problems in children. Secondary outcomes were improved mental health of the parents and sense of competence in parenting.

The General Health Questionnaire 12 (GHQ-12) is a 12-item version of the original GHQ and measures parents’ mental health. The GHQ is a psychometric self-administered screening device to measure psychiatric distress experienced by an individual over the past few weeks. Parents answered each item on a four-point Likert scale ranging from 1 (e.g., better than usual) to 4 (e.g., much less than usual), with higher scores indicating higher mental health distress. A total score is calculated by summing up all the items (total scores can range from 12 to 48).

The Parenting Sense of Competence (PSOC) scale was used to measure the participating parents’ sense of competence in parenting. The PSOC comprises 16 items divided into two subscales (satisfaction with nine items and efficacy with seven items). Parents responded on a six-point Likert scale anchored at 1=strongly disagree and 6=strongly agree. The total score ranged from 9 to 54 for the satisfaction items and 7 to 42 for the efficacy items. The satisfaction items were reverse coded; a higher score in both satisfaction and efficacy subscales indicates a higher parent sense of competence.

Participants were also asked about their sociodemographic background (e.g., age, sex, marital status, education level, number of years in Sweden, employment status, residential area, visits to cultural and community events, financial situation, number of children, children’s age...

GHQ, General Health Questionnaire; PSOC, Parenting Sense of Competence scale.

and sex). Both instruments (the GHQ-12 and the PSOC) were translated according to international guidelines. Approval to translate and use the GHQ-12 was obtained from instrument developers.

Sample size
Sample size was calculated based on the primary outcome, that is, reduced emotional and behavioural problems in the children with a medium effect size (Cohen’s d=0.5). The findings of the primary outcome measure have been published elsewhere. A sample of 128 parents/children (n=64 in the intervention group, n=64 in the control group) were required with alpha set at p<0.05 and power at 0.80.

Randomisation
The randomisation list was prepared using a computer sequence generator programme with permuted blocks to determine sequence numbers for allocation to the intervention and wait-list control group. Block randomisation, using blocks of 10, was done to obtain an equal distribution. Group affiliation and study number were noted on a piece of paper and placed in a set of identical opaque envelopes by the first author (FO). The envelopes were then sealed and shuffled. Thus, this procedure ensured that the content of each envelope was not known to either the researchers or the participants.

Randomisation was performed after the baseline data were collected by the first author and research

GHQ, General Health Questionnaire.
baseline to the 2-month follow-up was then tested with $\chi^2$ tests by comparing the proportion of parents in the intervention and control group who had deteriorated, remained unchanged or improved in mental health as well as in efficacy and satisfaction.

A stepwise approach was taken to identify which independent variables (ie, parental efficacy or parental satisfaction) should be included in the mediation model. In the first step, a regression analysis was conducted with change in mental health as the dependent variable and group membership (intervention or control group), parental satisfaction and efficacy as the independent variables. In this regression, only parental satisfaction (a path) emerged as a significant predictor of change in parental mental health. Indirect effect=direct effect of the intervention on change in parental mental health. Indirect effect=total effect−direct effect. Total effect=direct effect+indirect effect.

**RESULTS**

The study started May 2014 and ended in October 2015. In total, 149 parents were assessed for study eligibility and 120 parents were randomly assigned to the intervention group (n=60 parents) and the control group (n=60 parents). Of these 120 parents, 109 (90%) were successfully followed-up (57 in the intervention group and 52 in the control group). Of the 60 parents randomised to the intervention group, two did not attend any session and these could not be reached for follow-up. Overall, 70% of the parents (n=80) attended more than eight sessions. Few participants (30%) opted to use the child care services and support system (eg, to have the child care services read letters from the municipality during the 12 group-based sessions). The participation flowchart of each group is represented in figure 1.

**Participant characteristics at baseline**

**Table 1** presents the sociodemographic background of the respondents. There were no differences between the intervention and control groups in sociodemographic background. Most of the parents (98.3%, n=118) were biological parents of the child in the study. Of the parents who participated in the study, the majority had lived in Sweden between 1 and 5 years, had less than an upper secondary level of education and lived in a low socioeconomic status area.

There were no significant differences between the two groups or between fathers and mothers in financial strain, or baseline measures of mental health, efficacy and satisfaction in their parenting.

**Effects of the intervention on parents’ mental health and sense of competence**

The ANCOVA analyses (**table 2**) indicated that the parents in the intervention group had improved their mental health more than the parents in the control group 2 months after the intervention (95% CI, 2.02 to 5.18). The associated effect size was large (Cohen’s $d=0.85$). Similarly, the intervention had a positive effect on parents’ sense of competence in parenting. Parents in the intervention group reported greater improvements in both their parenting efficacy (95% CI −8.15 to −5.29; $d=1.79$) and satisfaction (95% CI −4.48 to −2.69; $d=0.89$) compared with parents in the control group.

**Clinical significance change**

**Table 3** shows the results from the clinical significance analysis. Although most parents remained unchanged, 12 parents (21%) in the intervention group demonstrated reliable improvement (measured by the GHQ-12) compared with only four (8%) in the control group. The positive changes were more pronounced for sense of competence in parenting with 29 (51%) parents in the intervention group showing reliable improvement (measured by the GHQ-12) compared with 12 parents in the control group. Of these 29 parents, 22 (38%) showed improvement in parenting efficacy and the remaining seven (12%) showed improvement in parental satisfaction.
Mediation model

The mediation analysis (figure 2) demonstrated a significant direct relation between the intervention and change in parental mental health ($c$ path, $\beta=-3.02, p=0.003$). In addition, the intervention had a positive association with parental satisfaction ($a$ path, $\beta=5.34, p<0.001$). In turn, parental satisfaction had a significant relation with change in parental mental health ($b$ path) when group assignment was controlled ($\beta=-0.17, p=0.05$). When the intervention effect and parental satisfaction were entered simultaneously in the last regression, a significant indirect effect ($ab$ paths) was found from the intervention effect to change in parental mental health through parental satisfaction ($\beta=-0.88, 95\% CI -1.84 to -0.16, p=0.047$), indicating that the intervention effect on parental mental health was partially mediated by parental satisfaction. Finally, the total effect of change on parents’ mental health ($c$ path) was significant ($\beta=-3.90, p<0.001$), indicating that parents who received the intervention had improved mental health. The model explained 16% ($R^2$ 0.16, $p<0.001$) of the change in parents’ mental health.

DISCUSSION

Our study shows that a culturally tailored parenting support programme improved the mental health and sense of competence in parenting of Somali-born parents 2 months after the intervention. These improvements were both statistically significant and clinically meaningful. The findings also indicate that parental satisfaction was a mediating factor in parents’ mental health.

Our findings are consistent with findings of earlier that show parenting programmes are generally effective in improving parents’ mental health but disagrees with some other studies in which parenting support programmes for immigrant parents did not have positive effects on parents’ mental health. For example, a trial conducted on immigrant mothers from Pakistan and Somalia showed that the parenting support programme was not effective in alleviating maternal mental distress. The most likely explanation for the positive effect is that the culturally tailored societal information addressed an important need for Somali-born parents. Previous studies have reported that immigrant parents encounter obstacles in their parenting in the host country (eg, insufficient information about the parenting system, role change and power conflict between parents and children, all of which contribute to stress in parenting). A second possible explanation is that the parenting intervention was culturally tailored (eg, the role plays and reflection exercises in the Connect programme). These role plays and reflection exercises were made more culturally understandable by using metaphors and proverbs (the Somali culture is in part characterised by oral tradition of poetry and narrative). Using the metaphors and proverbs can have a powerful impact on learning and understanding when employing complex or theoretical terms. A third explanation is that the group leaders who delivered the intervention had a similar background as the participating parents and were therefore ‘culturally tailored’ to the parents. Several studies have underlined the importance of finding ways to retain ethnic minorities and immigrants and to make the parenting programmes more attractive and effective. The group leaders were bilingual and were familiar with both Somali and Swedish cultures, which were strengths as nothing was ‘lost in translation’. A trial from Norway and a meta-analytic review suggest that parenting support programmes appear to be more effective when they are tailored to the specific challenges and needs of immigrant parents (ie, delivered to participants in their own language and by group leaders of a similar background). A final possible explanation is the focus of the parenting programme Connect, which encourages parents to reflect on their parenting role and develop sensitivity towards their children’s behaviour. Parents are taught to think and better understand the reason behind the child’s emotional reactions and to develop awareness on how to respond in a way that acknowledges the child’s attachment needs. Our qualitative study shows that parents requested support to strengthen the relationship with their children in the new host country.

Our findings demonstrate that parents’ sense of competence in parenting improved with a large effect size ($d=0.89$) in parental satisfaction and a huge effect size ($d=1.79$) in parental self-efficacy. Additionally, parental satisfaction mediated the intervention effect on change in parental mental health. Strong feelings of self-efficacy and satisfaction in parenting lead to positive mental health and parenting practices. Studies have suggested that immigrant parents who encounter challenges in acculturating within the host environment experience stress in parenting, which is an ample reason to feel a lower level of sense of competence in parenting and in mental health. Satisfaction in parenting is one factor among others that impact parents’ mental health. The mental health of parents is affected by other factors as well, including acculturation, social capital, social isolation and experiencing discrimination because of race or ethnicity. However, we hypothesise that with increased parental satisfaction, parents gain greater optimism in their parenting, which, in turn, affects their mental health as confirmed by a recent Swedish study.

From a clinical and practical standpoint, it is important to acknowledge the extent to which the intervention improved parents’ mental health and sense of competence in parenting. According to Jacobson and Truax, statistically significant and large effect sizes do not necessarily translate into clinically meaningful changes (ie, an intervention effect may be statistically significant but clinically trivial). The results of the reliable change analyses indicate that the intervention had indeed led to clinically meaningful changes in parental mental health and in a sense of competence in parenting.

There are several strengths and limitations to this study. One of the strengths is our use of an RCT research design.
to reduce selection bias and spurious causality inferences. Another strength was the low dropout rate and that we retained almost all parents (90%) at the 2-month follow-up. Furthermore, two-thirds of the parents attended more than eight sessions. A contributing factor to the low dropout rate and high rate of participation was the involvement of civil society (such as key people within Somali associations and having different information meetings about the research project). Furthermore, the group sessions were led by group leaders of Somali background who shared the same language and culture as the parents. One limitation is the short interval between the intervention and the follow-up. Another limitation is that the data were collected using a self-report measure. This study can be generalised to Somali-born parents who have experienced war or social conflict and stress in parenting, and the cultural sensitive model in this study can be applied and generalised to hard-to-reach groups.

Conclusions and implications for clinical practice

This study found that culturally tailored parenting support programme improved the mental health and sense of competence in parenting in Somali-born adults, with large effect sizes 2 months after the intervention ended. Our study highlights the importance of acknowledging immigrant parents' need for societal information in parent support programmes and that these programmes must be delivered in a culturally sensitive way. Improving the parents' mental health and sense of competence in parenting is associated with a positive effect on children's behavioural problems and the parent–child relationship, which promotes equity in health. The current study shows that a culturally tailored programme can be offered to all parents with self-perceived parenting-related stress, regardless of whether their children have emotional or behavioural problems or not. These findings underscore the beneficial effects of making culturally tailored parenting programmes accessible to immigrant parents.

ACKNOWLEDGEMENTS

The authors would like to thank all the parents who participated in this study, including Somali non-profit associations (eg, UMIS) and key persons who assisted with the information meetings and recruitment process. We also would like to thank all the group leaders who delivered the intervention and the data collectors for assisting in data collection. We thank the Public Health Agency of Sweden for funding this study.

Contributors
FO, MK-A, U-KS and RF conceptualised and designed the study and directed the planning and implementation of the trial. FO collected the data. RS and FO were responsible for data analyses and interpretation in which RF contributed to interpretation of the results. FO produced the draft manuscript to which all authors contributed and provided feedback during its development. All authors approved the final manuscript as submitted.
